

How to Run ISO Files Directly From the HDD with GRUB2

MTE maketecheasier.com/run-iso-files-hdd-grub2

```
#!/bin/sh
exec tail -n +3 $0
# This file provides an easy way to add custom menu entries.  Simply type the
# menu entries you want to add after this comment.  Be careful not to change
# the 'exec tail' line above.

menuentry "Kubuntu 15.04" {
set isopath="/home/maketecheasier/TempISOs/kubuntu-15.04-desktop-amd64.iso"
echo "Booting ${isopath}..."
loopback loop (hd0,1)$isopath
linux (loop)/casper/vmlinuz.efi boot=casper iso-scan/filename=${isofile} quiet splash
initrd (loop)/casper/initrd.lz
}
```

Most Linux distros offer a live environment, which you can boot up from a USB drive, for you to test the system without installing. You can either use it to evaluate the distro or as a disposable OS. While it is easy to copy these onto a USB disk, in certain cases one might want to run the same ISO image often or run different ones regularly. GRUB 2 can be configured so that you do not need to burn the ISOs to disk or use a USB drive, but need to run a live environment directly from the boot menu.

Obtaining and checking bootable ISO images

To obtain an ISO image, you should usually visit the website of the desired distribution and download any image that is compatible with your setup. If the image can be started from a USB, it should be able to start from the GRUB menu as well.

Once the image has finished downloading, you should check its integrity by running a simple md5 check on it. This will output a long combination of numbers and alphanumeric characters

```
maketechasier@attila-VirtualBox: ~/TempISOs
maketechasier@attila-VirtualBox:~/TempISOs$ ls
kubuntu-15.04-desktop-amd64.iso
maketechasier@attila-VirtualBox:~/TempISOs$ md5sum kubuntu-15.04-desktop-amd64.iso
106d890bcad20433685b0bd76f95b4ab kubuntu-15.04-desktop-amd64.iso
maketechasier@attila-VirtualBox:~/TempISOs$
```

which you can compare against the MD5 checksum provided on the download page. The two should be identical.

Setting up GRUB 2

ISO images contain full systems. All you need to do is direct GRUB2 to the appropriate file, and tell it where it can find the kernel and the initramdisk or initram filesystem (depending on which one your distribution uses).

In this example, a Kubuntu 15.04 live environment will be set up to run on an Ubuntu 14.04 box as a Grub menu item. It should work for most newer Ubuntu-based systems and derivatives.

In this example the file `kubuntu-15.04-desktop-amd64.iso`

lives in `/home/maketechasier/TempISOs/` on `/dev/sda1` .

To make GRUB2 look for it in the right place, you need to edit the

`/etc/grub.d/40_custom`

file which allows you to add your own menu entries. The file should already exist and contain a few lines.

```
mc [root@attila-VirtualBox]:/etc/grub.d
GNU nano 2.2.6      File: /etc/grub.d/40_custom      Modified

#!/bin/sh
exec tail -n +3 $0
# This file provides an easy way to add custom menu entries.  Simply type the
# menu entries you want to add after this comment.  Be careful not to change
# the 'exec tail' line above.
```

To start Kubuntu from the above location, add the following code (after adjusting it to your needs) below the commented section, without modifying the original content.

```
menuentry "Kubuntu 15.04 ISO" {
set isofile="/home/maketecheasier/TempISOs/kubuntu-15.04-desktop-amd64.iso"
loopback loop (hd0,1)$isofile
echo "Starting $isofile..."
linux (loop)/casper/vmlinuz.efi boot=casper iso-scan/filename=${isofile} quiet splash
initrd (loop)/casper/initrd.lz
}
```

```
mc [root@attila-VirtualBox]:/etc/grub.d
GNU nano 2.2.6      File: /etc/grub.d/40_custom      Modified

#!/bin/sh
exec tail -n +3 $0
# This file provides an easy way to add custom menu entries.  Simply type the
# menu entries you want to add after this comment.  Be careful not to change
# the 'exec tail' line above.

menuentry "Kubuntu 15.04" {
set isopath="/home/maketecheasier/TempISOs/kubuntu-15.04-desktop-amd64.iso"
echo "Booting ${isopath}..."
loopback loop (hd0,1)$isopath
linux (loop)/casper/vmlinuz.efi boot=casper iso-scan/filename=${isofile} quiet splash
initrd (loop)/casper/initrd.lz
}
```

Breaking down the above code

First set up a variable named `$menuentry`. This is where the ISO file is located. If you want to change to a different ISO, you need to change the bit where it says set `isofile="/path/to/file/name-of-iso-file-.iso"`.

The next line is where you specify the loopback device; you also need to give it the right partition number. This is the bit where it says

```
loopback loop (hd0,1)$isofile
```

Note the `hd0,1` bit; it is important. This means first HDD, first partition (`/dev/sda1`).

GRUB's naming here is slightly confusing. For HDDs, it starts counting from "0", making the first HDD #0, the second one #1, the third one #2, etc. However, for partitions, it will start counting from 1. First partition is #1, second is #2, etc. There might be a good reason for this but not necessarily a sane one (UX-wise it is a disaster, to be sure)..

This makes first disk, first partition, which in Linux would usually look something like `/dev/sda1` become `hd0,1` in GRUB2. The second disk, third partition would be `hd1,3`, and so on.

The next important line is

```
linux (loop)/casper/vmlinuz.efi boot=casper iso-scan/filename=${isofile} quiet splash
```

It will load the kernel image. On newer Ubuntu Live CDs, this would be in the `/casper` directory and called `vmlinuz.efi`. If you use a different system, your kernel might be missing the `.efi` extension or be located somewhere else entirely (You can easily check this by opening the ISO file with an archive manager and looking inside `/casper`). The last options, `quiet splash`, would be your regular GRUB options, if you care to change them.

Finally

```
initrd (loop)/casper/initrd.lz
```

will load `initrd`, which is responsible to load a RAMDisk into memory for bootup.

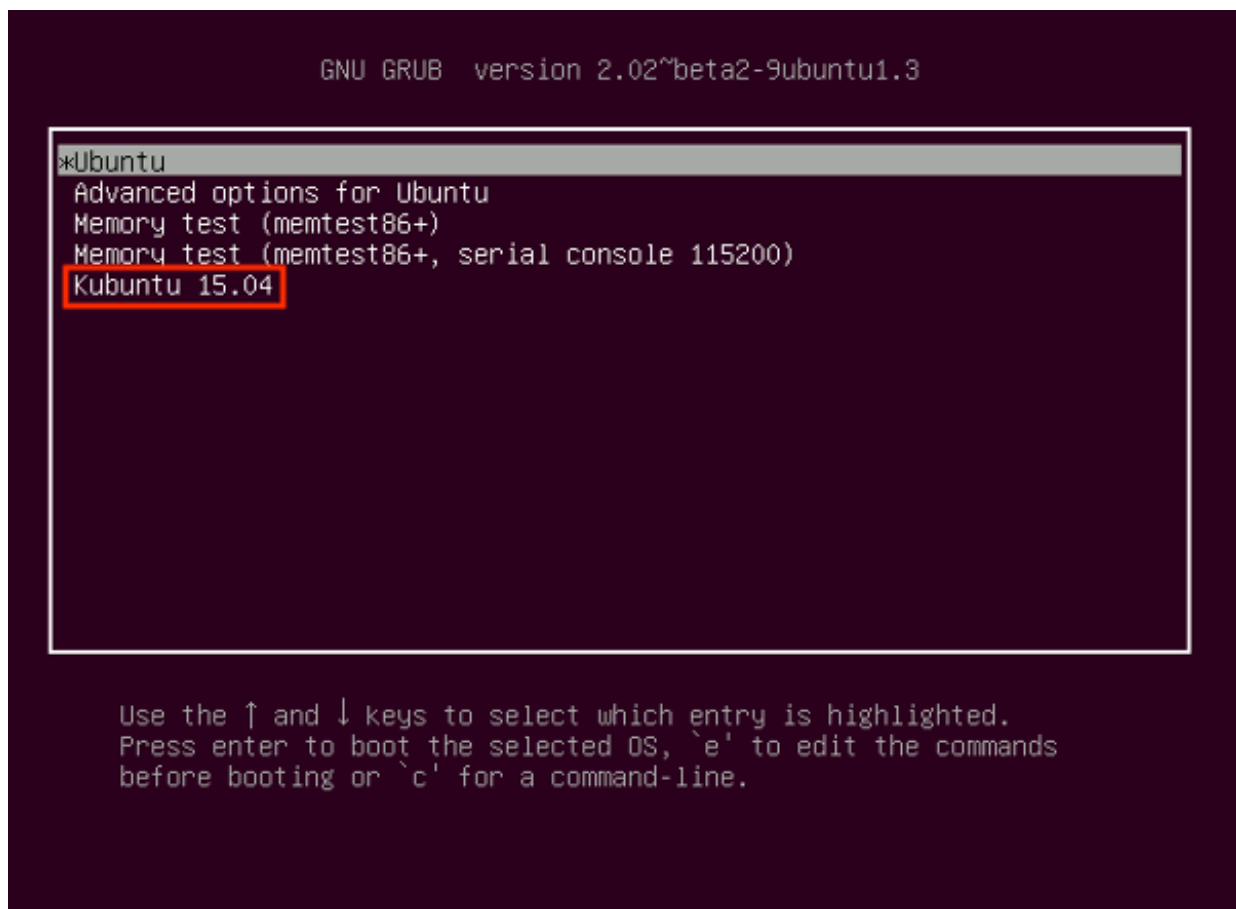

Booting into your live system

To make it all work, you will only need to update GRUB2

```
sudo update-grub
```

```
maketecheasier@attila-VirtualBox: ~  
maketecheasier@attila-VirtualBox:~$ sudo update-grub  
Generating grub configuration file ...  
Warning: Setting GRUB_TIMEOUT to a non-zero value when GRUB_HIDDEN_TIMEOUT is set is  
no longer supported.  
Found linux image: /boot/vmlinuz-3.16.0-37-generic  
Found initrd image: /boot/initrd.img-3.16.0-37-generic  
Found linux image: /boot/vmlinuz-3.16.0-30-generic  
Found initrd image: /boot/initrd.img-3.16.0-30-generic  
Found memtest86+ image: /boot/memtest86+.elf  
Found memtest86+ image: /boot/memtest86+.bin  
done  
maketecheasier@attila-VirtualBox:~$
```

When you reboot your system, you should be presented with a new GRUB entry which will allow you to load into the ISO image you've just set up.

Selecting the new entry should boot you into the live environment, just like booting from a DVD or USB would.
